## Virtual Instrumentation

The following design note is an example of a method used to display measurement information that has the “look” of instrumentation. This program is taken from a larger program that was developed using Bascom-Avr. The design monitors wind speed/direction. This design note will only focus on the display portion, so the code for the wind instruments has been replaced with a user input from a terminal. The wind direction information is displayed in the form of a virtual compass. The dial is a circle with the compass directions displayed. The indicator is an arrow in the center of the dial that points in the direction of the wind. The wind-speed indicator is displayed using a vertical level bar that has a range between 0 and 100 mph. In addition to the graphical depiction, text information is also displayed. The following code can easily be modified to produce different gauges to display other types of measurement info.

**Figure 1.** Windmeter

**Figure 2.** Schematics

## Code

```
***partial code for a wind meter(graphical part)
$crystal = 4000000
